An image of the Tomcat Java application server

This screenshot shows the search results for "tomcat" on Docker Hub. The first result is the "tomcat" Docker Official Image, which is prominently displayed with a yellow cat icon. It has over 500 million downloads. The second result is a custom image named "jelastic/tomcat" by jelastic, which has 10 million downloads and 4 stars. Both cards show the supported architectures (Linux, x86-64, ARM, ARM 64, PowerPC 64 LE, IBM) and the last update time (3 days ago for the official image, 6 days ago for the jelastic image).

# Which Docker image to choose?

A screenshot of the Docker Hub website. At the top, there's a search bar with a magnifying glass icon and the word "tomcat". Below the search bar, there are three navigation tabs: "Docker", "Containers" (which is highlighted in blue), and "Plugins".

# Characterizing the Occurrence of Dockerfile Smells in Open-Source Software: An Empirical Study

YIWEN WU<sup>1</sup>, YANG ZHANG<sup>2</sup>, TAP WANG<sup>3</sup>, AND HUAIMIN YING<sup>4</sup>

Key Laboratory of Software Engineering of Ministry of Education, Wuhan University, China  
Corresponding author: Yang Zhang (zhangyang@whu.edu.cn)

This work was supported in part by the Program of a New Generation of Artificial Intelligence 2019 under Grant 2019AA010730,  
the National Science and Technology Major Project of China under Grant 01421100000, and in part by the National Natural Science Foundation of China under  
Grant 61702532.

**ABSTRACT** Dockerfile plays an important role in the Docker-based software development process, but many smells can be reflected with smells in practice. Understanding the occurrence of Dockerfile smells in open-source software can benefit the practice of Dockerfile and enhance project maintenance. In this paper, we perform an empirical study on a large dataset of 6,334 projects to help developers gain some insights into the occurrence of Dockerfile smells, including its coverage, distribution, co-occurrence, and correlation with project characteristics. Our results show that smells are very common in Dockerfile codes and there exists co-occurrence between different types of Dockerfile smells. Further, using linear regression analysis, when controlled for various variables, we statistically identify and quantify the relationships between Dockerfile smells occurrence and project characteristics. We also provide a rich resource of implications for software practitioners.

**INDEX TERMS** Docker, Dockerfile smells, Open-source software, GitHub.

## L INTRODUCTION

“There are over one million Dockerfiles on GitHub today, but not all Dockerfiles are created equally.” — Tibor Vass<sup>1</sup>

Docker<sup>2</sup>, as one of the most popular containerization tools, enables the encapsulation of software packages into containers. Dockerfiles are the primary configuration files that define a dependency- and execution environment into a standardized, self-contained unit, which can be used for software development and to run the application on any system [2]. Since inception in 2013, Docker containers have gained 32,000+ GitHub stars and have been downloaded 105B+ times<sup>3</sup>. The “Annual Container Adoption” report<sup>4</sup> found that 79% of companies chose Docker as their primary container technology. The contents of a Docker container are defined by

declarations in the Dockerfile [3] which specifies the Docker commands and the order of their execution, following the notion of Infrastructure-as-Code (IaC) [4]. Thus, studying Dockerfile is very relevant to Docker-based software development.

Code smells [5] indicate the presence of quality problems in a software project. Recently, smell metaphor has been extended to various related sub-domains of software, e.g., database [6], logging [7], and continuous integration [8]. Typically, when developing and writing a Dockerfile, developers thoroughly read Docker’s official documentation best practices for Dockerfile<sup>5</sup>. Although such guideline covers the recommended best practices and methods, it is still challenging for developers to fully follow the recommended rules due to lack of awareness and attention. Therefore, similar to regular code, Dockerfile code can also indicate smells. However, the presence/absence of Dockerfile smells in OSS projects and their relationships with project characteristics

### I. INTRODUCTION

The container technology has become a popular technology to achieve distributed applications across a single host or multiple hosts. Containerization, originated from the virtual machine technology, has been widely adopted in cloud computing and big data processing. However, it is also associated with many security issues. Therefore, it is necessary to identify and mitigate the security risks of containerization. To address the above challenges, researchers have conducted many studies to improve the security of containerization. For example, researchers have proposed various methods to detect Dockerfile smells, such as Dockerfile smells detection, Dockerfile smells classification, Dockerfile smells removal, and Dockerfile smells prevention. These methods have been widely adopted in the field of Dockerfile smells detection. However, there is still a lack of research on Dockerfile smells prevention. Therefore, it is necessary to propose effective methods to prevent Dockerfile smells. In this paper, we propose a novel method to prevent Dockerfile smells based on Dockerfile smells detection and classification.

**ABSTRACT** Dockerfile plays an important role in the Docker-based software development process, but many projects are infected with smells in practice. Understanding the occurrence of Dockerfile smells in open-source software can benefit the practice of Dockerfile and enhance project maintenance. In this paper, we perform an empirical study on a large dataset of 6,334 projects to help developers gain some insights into the occurrence of Dockerfile smells, including coverage, distribution, co-occurrence, and correlation with project characteristics. Our results show that Dockerfile smells are very common in Dockerfile codes and there exists co-occurrence between different types of Dockerfile smells. By using linear regression analysis, when controlled for various variables, we statistically prove the relationships between Dockerfile smells occurrence and project characteristics, which provides implications for software practitioners.

**L. INTRODUCTION**

"There are over one million Dockerfiles on GitHub today, but not all Dockerfiles are created equally." — Tibor Varga

Docker<sup>1</sup>, as one of the most popular containerization technologies, enables the encapsulation of software packages into containers. Dockerfiles define how to package dependencies and execution environment into a self-contained unit, which can be used to develop and to run the application on any host system. Since inception in 2013, Docker containers have grown 32,000+ GitHub stars and have been downloaded over 100,000 times<sup>2</sup>. The "Annual Container Adoption" report<sup>3</sup> shows that 79% of companies chose Docker as their primary technology. The contents of a Docker contain-

Too many images on DockerHub! How different  
are images for the same system?

### Abstract

Containerization is a technique used to encapsulate a software system and its dependencies into one isolated package, which is called a container. The goal of these containers is to deploy or replicate a software system on various platforms and environments without facing any compatibility or dependency issues. Developers can instantiate these containers from images using Docker, one of the most popular containerization platforms. Furthermore, many of these images are publicly available on DockerHub, on which developers can share their images with the community who in turn can leverage such publicly available image. However, DockerHub contains thousands of images for each software system, which makes the selection of an image a nontrivial task. In this paper, we investigate the differences among DockerHub images for five software systems and 936 images with the goal of helping Docker tooling creators and DockerHub better guide users select a suitable image. We observe that users tend to download the official images (images that are provided by Docker itself) when there exist a large number of image choices for each single software system on the community images (images that are provided by the community developers), which are in many cases more resource efficient (have less duplicate resources) and have less security vulnerabilities. In fact, we observe that 27% (median), 35% (median), 6% (median), and 9% (median) of the DockerHub Debian, CentOS, Ubuntu, and Alpine based images are identical to another image across all the studied software systems. Furthermore, community images are more resource efficient than their respective official images across all the five studied software systems. 7% (median) of the community Debian based images have less security vulnerabilities than their respective official images across the four studied software systems, for which an official Debian based image exists. Unfortunately, the studied images do not guide users when selecting an image (the images do not highlight the particularities of the image), which makes it difficult for users to distinguish

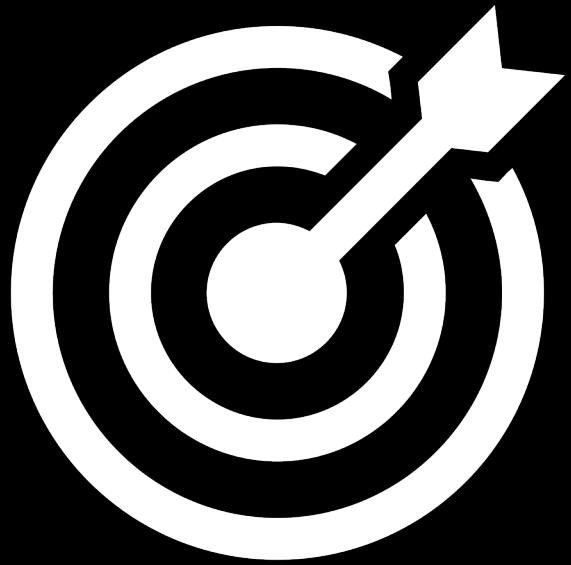

"smells are very common in Dockerfile codes"

"images contain more than 180 vulnerabilities on average"

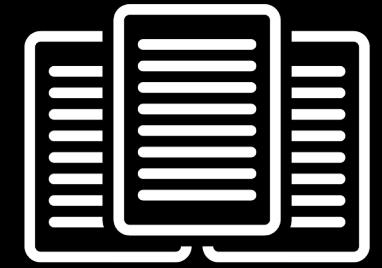

"community images are more resource-efficient and have fewer vulnerabilities"

What **quality features**  
characterize the adoption  
of a Docker image  
(and its Dockerfile)

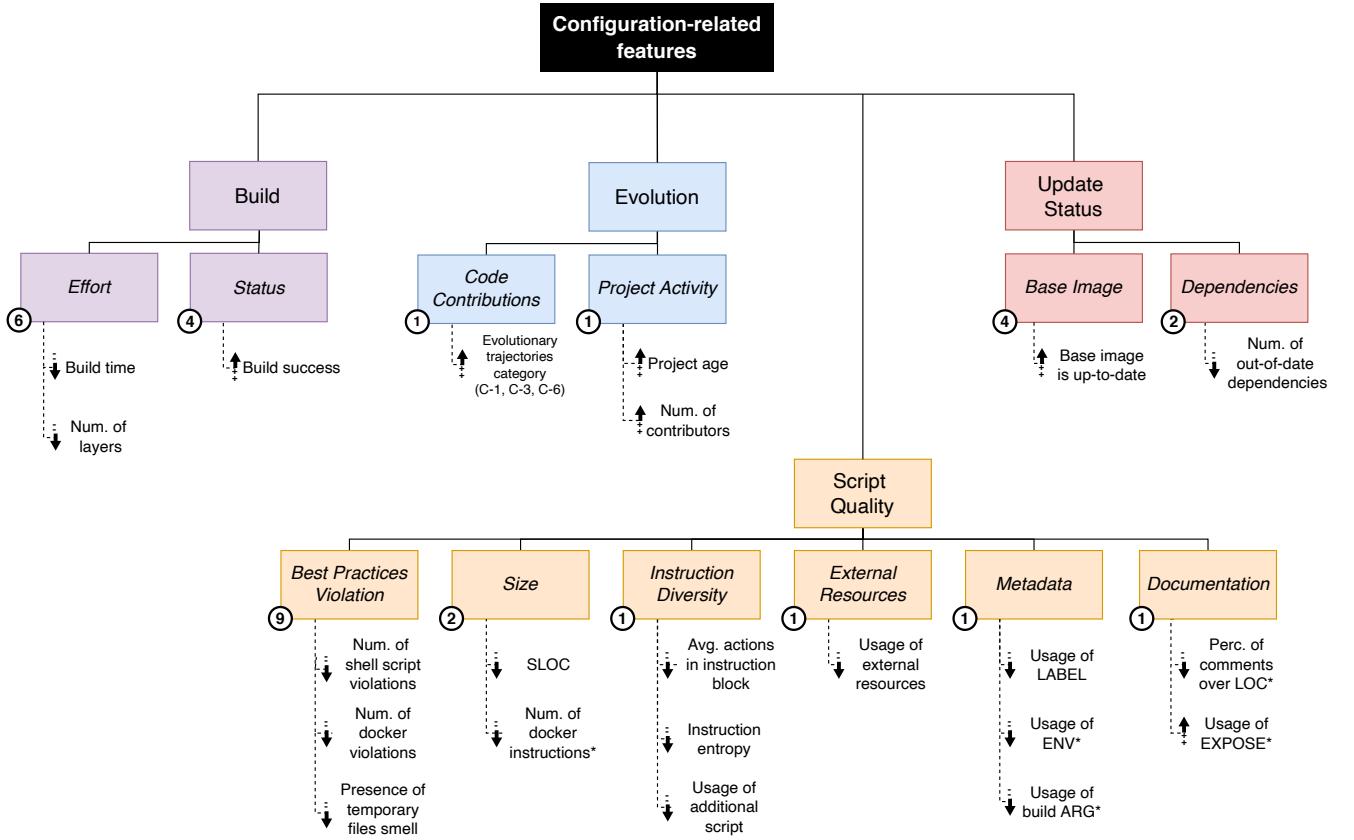

Step 1:

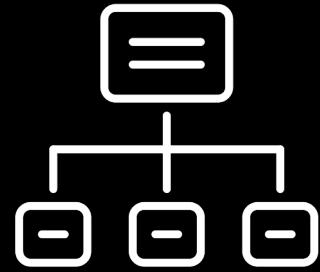

# Learning from the Literature

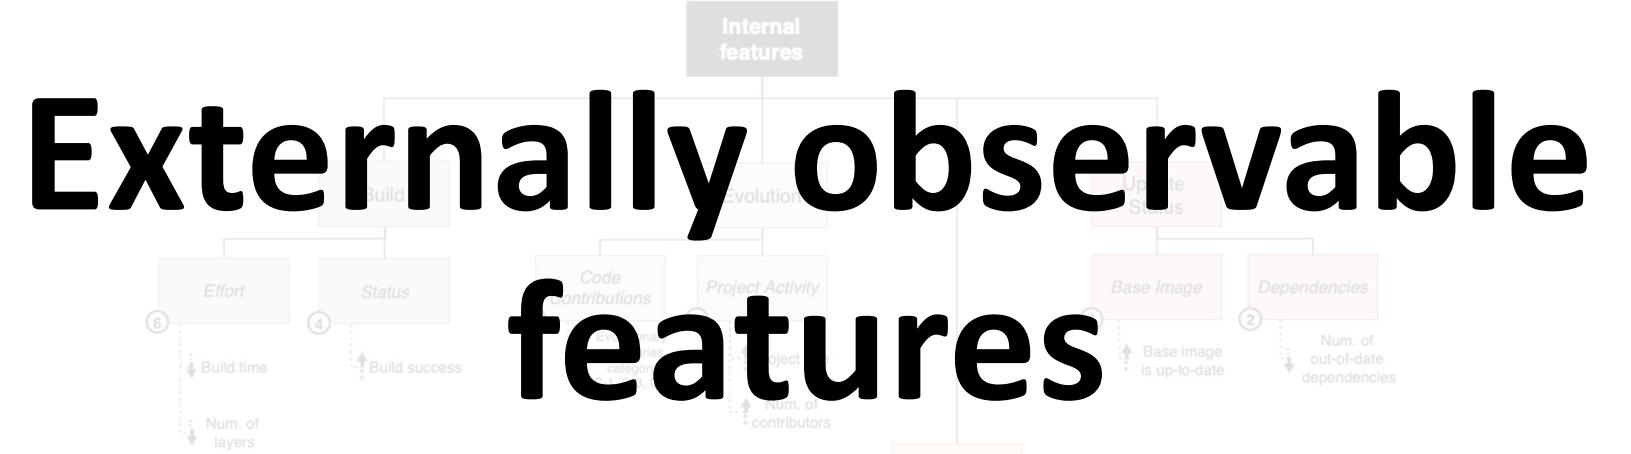

# Literature review

**31** papers

Taxonomy of quality metrics

e.g.

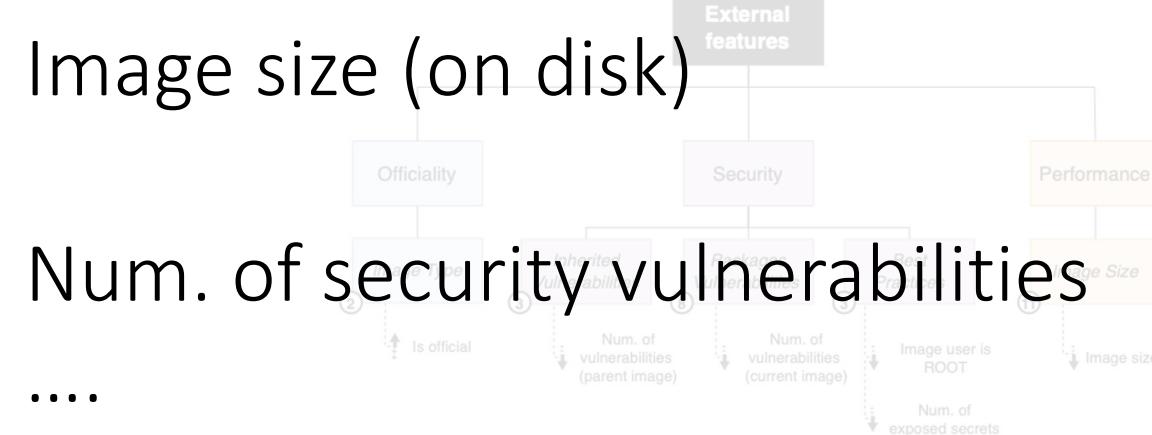

Has “official image” badge

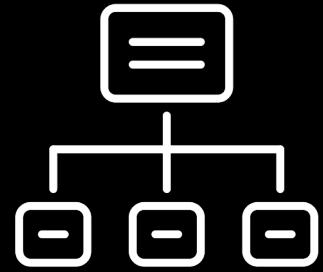

Image size (on disk)

Num. of security vulnerabilities

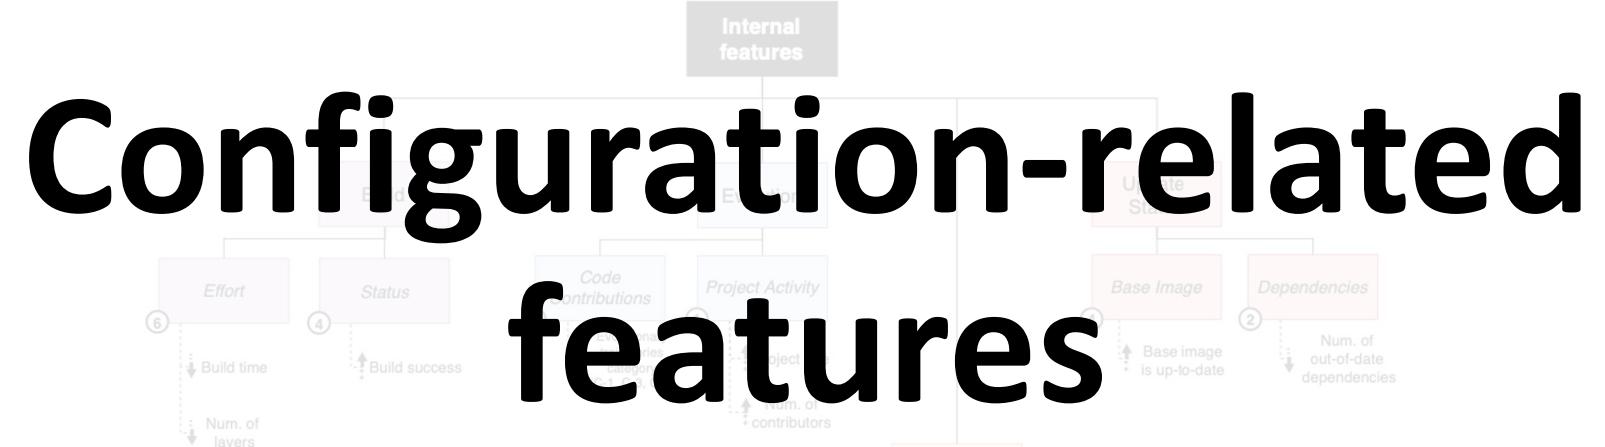

....

**6** metrics

Taxonomy of quality metrics

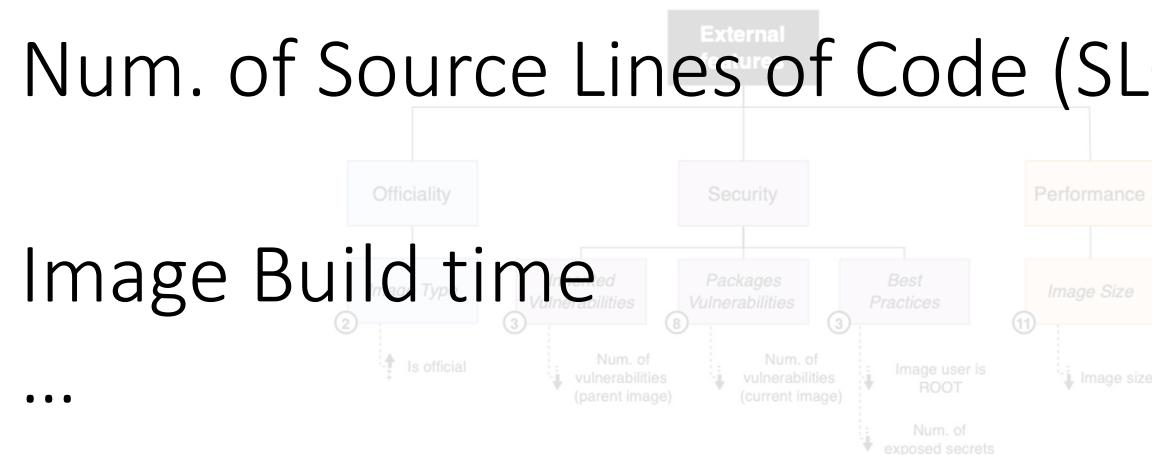

e.g.

Num. of Dockerfile Smells

Num. of Source Lines of Code (SLOC)

Image Build time

...

**22** metrics

Step 2:

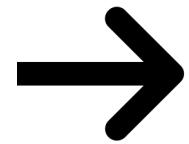

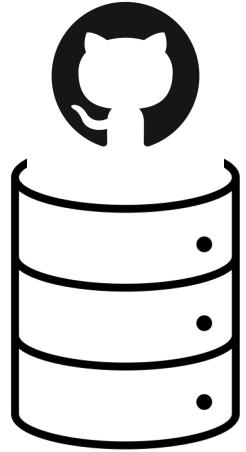

# Catching the Developers' Preferences

# RQ1

Can the externally observable features  
explain the developers' preference  
for a Docker image?

## RQ1: Context
